(57) ABSTRACT

A device for closing an aperture in a vessel wall comprising a covering member having a longitudinal axis and positionable inside the vessel against the internal opening of the aperture and having a dimension to prevent egress of fluid through the aperture and having a first opening. A first retainer is positionable external of the vessel. A flexible connecting member operatively connects the covering member and the first retainer, wherein the first opening of the covering member is configured to restrict movement of the connecting member.

VASCULAR HOLE CLOSURE DEVICE

This application is a continuation of patent application Ser. No. 12/854,988, filed Aug. 12, 2010 which claims priority from provisional application Ser. No. 61/241,555, filed Sep. 11, 2009 and is a continuation in part of application Ser. No. 12/358,411, filed Jan. 23, 2009, now U.S. Pat. No. 8,070,772 which claims priority from provisional application Ser. No. 61/066,072, filed Feb. 15, 2008. The entire contents of each of these applications are incorporated herein by reference.

BACKGROUND

1. Technical Field

This application relates to a vascular device and more particularly to a device for closing openings in vessel walls.

2. Background of Related Art

inserted through an incision in the skin and underlying tissue to access the femoral artery in the patient's leg. The catheter is then inserted through the access opening made in the wall of the femoral artery and guided through the artery to the desired site to perform surgical procedures such as angio- 25 plasty or plaque removal. After the surgical procedure is completed and the catheter is removed from the patient, the access hole must be closed. This is quite difficult not only because of the high blood flow from the artery, but also because there are many layers of tissue that must be pen- 30 etrated to reach the femoral artery.

Several approaches to date have been used to close femoral access holes. In one approach, manual compression by hand over the puncture site is augmented by a sandbag or weight until the blood coagulates. With this approach, it can 35 take up to six hours for the vessel hole to close and for the patient to be able to ambulate. This inefficiency increases the surgical procedure time as well as the overall cost of the procedure since the hospital staff must physically maintain pressure and the patient's discharge is delayed because of 40 the inability to ambulate.

In another approach to close the vessel puncture site, a clamp is attached to the operating table and the patient's leg. The clamp applies pressure to the vessel opening. The patient, however, must still be monitored to ensure the blood 45 is coagulating, requiring additional time of the hospital staff and increasing the cost of the procedure.

To avoid the foregoing disadvantages of manual pressure approaches, suturing devices have been developed. One such suturing device, sold by Abbott, advances needles 50 adjacent the vessel wall opening and pulls suture material outwardly through the wall adjacent the opening. The surgeon then ties a knot in the suture, closing the opening. One difficulty with the procedure involves the number of steps required by the surgeon to deploy the needles, capture the 55 suture, withdraw the suture, and tie the knot and secure the suture. Moreover, the surgeon cannot easily visualize the suture because of the depth of the femoral artery (relative to the skin) and essentially ties the suture knot blindly or blindly slips a pre-tied knot into position. Additionally, the 60 ability to tie the knot varies among surgeons; therefore success and accuracy of the hole closure can be dependent on the skill of the surgeon. Yet another disadvantage of this suturing instrument is that the vessel opening is widened for insertion of the instrument, thus creating a bigger opening to 65 close in the case of failure to deliver the closure system. It is also difficult to pass the needle through calcified vessels.

2

U.S. Pat. No. 4,744,364 discloses another approach for sealing a vessel puncture in the form of a device having an expandable closure member with a filament for pulling it against the vessel wall. The closure member is held in place by a strip of tape placed on the skin to hold the filament in place. However, the closure device is still subject to movement which can cause leakage through the puncture. Additionally, if the suture becomes loose, the closure member is not retained and can flow downstream in the vessel. Moreover, since the suture extends through the skin, a potential pathway for infection is created. The closure device in U.S. Pat. No. 5,545,178 includes a resorbable collagen foam plug located within the puncture tract. However, since coagulation typically takes up to twenty minutes and blood can leak in between the plug and tissue tract, manual pressure must be applied to the puncture for a period of time, until the collagen plug expands within the tract.

It would therefore be advantageous to provide a device During certain types of vascular surgery, catheters are 20 which would more quickly and effectively close openings (punctures) in vessel walls. Such device would advantageously avoid the aforementioned time and expense of applying manual pressure to the opening, simplify the steps required to close the opening, avoid widening of the opening, and more effectively retain the closure device in the vessel.

> Commonly assigned U.S. Pat. No. 7,662,161 discloses effective vascular hole closure devices which have the foregoing advantages. It would be further advantageous to provide a vascular hole closure device which is adjustable to accommodate different tissue thicknesses and applies a more constant clamping/retaining force between the intravascular and extravascular components of the device irrespective of tissue thickness.

SUMMARY

The present invention overcomes the disadvantages and deficiencies of the prior art. The present invention provides a device for closing an aperture in a vessel wall, the aperture having an external opening in an external region of the vessel wall and an internal opening in an internal region of the vessel wall. The device comprises a covering member positionable inside the vessel against the internal opening of the aperture and having a dimension to prevent egress of fluid through the aperture and having a first opening. A first retainer is positionable external of the vessel. A flexible connecting member operatively connects the covering member and the first retainer and advances the retainer toward the covering member. The first opening of the covering member is configured to restrict movement of the connecting mem-

Preferably the connecting member comprises a first suture and the first retainer is attached to the first suture whereby pulling of the first suture moves the first retainer toward the covering member.

The device may further comprise a second retainer movable toward the covering member by pulling a second suture attached to the second retainer. The covering member can have a second opening configured to restrict movement of the second suture. In preferred embodiments, the first and second retainers are spherical.

In preferred embodiments, the first and second retainers and the first and second sutures are composed of a resorbable material.

In a preferred embodiment, the retainers are positioned in a substantially side by side relationship in a placement position and are positioned in a stacked relationship in a delivery position.

In one embodiment, the opening has a dimension to ⁵ frictionally engage the connecting member. In another embodiment, the opening includes a plurality of teeth to retain the connecting member.

The covering member is preferably pivotable between a longitudinal orientation for delivery and a transverse position for placement

The device may include a third opening for unrestricted movement of the first suture and fourth opening for unrestricted movement of the second suture.

In another aspect, the present disclosure provides a method of closing an aperture in a vessel wall, the aperture having an external opening in an external region of the vessel wall and an internal opening in an internal region of the vessel wall. The method comprises the steps of:

inserting a covering member inside the vessel against the internal opening of the aperture, the covering member having a dimension to prevent egress of fluid through the aperture and having a connecting member extending therefrom;

inserting a first retainer external of the vessel; and applying a sufficient force to overcome resistance to movement of the connecting member to advance the first retainer toward the covering member.

In one embodiment, the step of advancing the first retainer comprises the step of moving a suture attached to the first retainer through an opening in the covering member having a diameter substantially the same as the outer diameter of the suture. The method preferably includes the steps of inserting a second retainer external of the vessel and advancing the second retainer toward the covering member by pulling a second suture connected to the second retainer.

In one embodiment, the step of advancing the first retainer comprises the step of moving a first suture attached to the first retainer through an opening having a plurality of teeth engagable with the outer surface of the suture. In another embodiment, the step of advancing the first retainer comprises the step of moving a first suture attached to the first retainer between bumps on the covering member.

BRIEF DESCRIPTION OF THE DRAWINGS

Preferred embodiment(s) of the present disclosure are described herein with reference to the drawings wherein:

FIG. 1 is a perspective view of a first embodiment of the 50 of an alternative embodiment; closure device of the present invention; FIG. 27 is a bottom view

FIG. 2 is a side perspective view of the covering (blocking) member of the closure device of FIG. 1 shown within a delivery sheath;

FIG. 3 is a side perspective view illustrating the covering 55 member of FIG. 2 deployed from the delivery sheath;

FIG. 4 is a side view illustrating one of the spherical retainers of the closure device deployed from the sheath (the vessel wall shown in cross-section);

FIG. 5 illustrates both spherical retainers deployed from 60 the sheath;

FIG. 6 illustrates the sutures pulled to move the spherical retainers toward the covering member for positioning in a side by side relationship against the outer surface of the vessel wall;

FIG. 7 is a perspective view illustrating the retainers in the placement position;

4

FIG. 8 is a perspective view of the covering member and sutures of an alternate embodiment of the closure device of the present invention showing the sutures attached to the covering member via a looped suture;

FIG. 9 is a perspective view illustrating an alternate orientation of the retainers in the placement position;

FIG. 10 is a perspective view of another alternate embodiment of the closure device of the present invention;

FIGS. 11-13C illustrate schematically the steps of insertion of the closure device of FIG. 10 (the delivery sheath not shown for clarity) wherein:

FIG. 11 illustrates the covering member distal of the retainer tube and the retainers inside the retainer tube;

FIG. 12 illustrates the retainers advanced from the retainer tube;

FIG. 13A illustrates the first retainer being advanced towards the covering member;

FIG. **13**B illustrates the first retainer further advanced 20 toward the covering member;

FIG. 13C illustrates the second retainer advanced toward the covering member;

FIG. 14 is a perspective of yet another alternate embodiment of the closure device of the present invention;

FIG. 15 is a cross-sectional view taken along lines 15-15 of FIG. 14;

FIG. **16** is a bottom view of the covering member of FIG.

FIG. 17 is a top view of a portion of the covering member of FIG. 14 with the suture removed for clarity;

FIG. 18 is a cross-sectional view taken along lines 18-18 of FIG. 17.

FIG. 19 is a perspective view of yet another alternate embodiment of the closure device of the present invention;

FIG. 20 is an exploded view of the spherical retainers and sutures of FIG. 19;

FIG. 21 is a cross-sectional view taken along lines 21-21 of FIG. 19;

comprises the step of moving a first suture attached to the first retainer through an opening having a plurality of teeth member of an alternate embodiment of the present inventence and alternate embodiment of the present invention:

FIG. 23 is a close up view of the area of detail designated in FIG. 22;

FIG. **24** is a perspective view of another alternate embodiment of the closure device shown with the covering member plug separated from the covering member;

FIG. 25 is a perspective view of the assembled closure member of FIG. 24;

FIG. **26** is a top view of a region of the covering member of an alternative embodiment;

FIG. 27 is a bottom view of a region of the covering member of another alternative embodiment;

FIG. 28 is a perspective view of an alternate embodiment of the closure device of the present invention;

FIG. 29 is a side view of the closure device of FIG. 28;

FIG. 30 is a bottom view of the closure device of FIG. 28;

FIG. 31 is a cross-sectional view of the covering member of the closure device of FIG. 28;

FIG. 32 is a cross-sectional view illustrating attachment of the retainer and suture;

FIG. 33 is a cross-sectional view illustrating an alternate attachment of the retainer and suture;

FIG. 34 is a cross-sectional view illustrating another alternate attachment of the retainer and suture; and

FIG. **35** is a perspective view of another alternate embodiment of the closure device of the present invention utilizing the retainer/suture attachment of FIG. **34**.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

Referring now in detail to the drawings where like reference numerals identify similar or like components throughout the several views, FIG. 1 is a perspective view of a first embodiment of the vascular hole (aperture) closure device of the present invention. The device is intended to close an aperture in the vessel wall, typically formed after removal of a catheter previously inserted through the vessel wall into the vessel lumen for performing angioplasty or other interventional procedures. The aperture extends through the patient's skin and underlying tissue, through the external wall of the vessel, through the wall of the vessel, and through the internal wall of the vessel to communicate with the internal lumen of the vessel. The closure device of the present invention has an intravascular component to block blood flow and an extravascular component to retain the intravascular component.

More specifically, the closure device includes a covering member or patch positioned within the vessel against the internal wall of the vessel to block blood flow and two retainers positioned external of the vessel wall to retain the covering member in its blocking position. Each retainer is 25 preferably spherical in configuration and is fixedly attached to a suture such that pulling of the suture advances the attached retainer toward the covering member to ultimately position the retainers in a side by side relationship either against or adjacent the external surface of the vessel wall. 30

Turning to FIGS. 1-7, a first embodiment of the closure device of the present invention is illustrated. Hole (aperture) closure device 10 has a covering (blocking) member or patch 40 and first and second retainers 20, 22. First and second retainers 20, 22 are preferably in the form of a sphere 35 or ball. The covering member 40 is dimensioned and configured for positioning inside the vessel on the internal side of the vessel aperture against the internal wall of the vessel; the retainers 20, 22 are configured to be positioned outside the vessel wall adjacent or contiguous the external side of 40 the vessel aperture.

Covering member 40, preferably elongated in configuration as shown, is retained in a delivery sheath in a longitudinal position for delivery to the vessel, and then pivots to a transverse position within the vessel lumen (substantially 45 perpendicular to an axis extending through the aperture) for orientation to cover (patch) the vessel aperture on the internal side. This movement is illustrated in FIGS. 37A-37D of U.S. Pat. No. 7,662,161, the entire contents of which are incorporated herein by reference (hereinafter the '161 50 patent). A comparison of FIGS. 2 and 5 also shows pivoting of the covering member.

The spherical retainers are preferably held in the delivery tube in a stacked relationship (see e.g. FIG. 11), with retainer 22 (222) atop retainer 20 (220) (or vice versa).

The elongated covering member 40 functions to cover (patch) the internal opening in the vessel wall to prevent the egress of blood. With reference to FIGS. 1 and 4, the covering member 40 is preferably somewhat oval shaped with elongated substantially parallel side walls 42a, 42b and 60 end walls 44a, 44b connecting the side walls 42a, 42b. Other shapes of the covering member are also contemplated. The end walls 44a, 44b can have substantially straight wall portions, or curved wall portions. Covering member preferably has a thicker region 43 in the central region than the first 65 and second end regions 45, 47. Other dimensions are also contemplated.

6

The longitudinal axis of covering member 40 defines a lengthwise dimension and transverse axes define a shorter widthwise dimensions. The widthwise dimension of the covering member 40 is preferably, for a 6 Fr device, in the range of about 2.5 mm to about 3.5 mm, and more preferably about 3.3 mm. Other dimensions are also contemplated. The width preferably is at least substantially equal to the dimension of the internal opening in the vessel wall to effectively cover the opening. In a preferred embodiment, the covering member 40 has a length in the range of about 7.5 mm to about 9 mm (in a 6 French system), and preferably about 8 mm

It should be appreciated that alternatively the covering member could be provided with an enlarged width region as illustrated in the embodiment of FIG. 1 of the '161 patent. The covering member could also be configured asymmetrically so that the enlarged region is off-centered to accommodate widening of the aperture as the member is pulled at an angle. The covering member could also be configured in a paddle shaped with a narrowed region adjacent a wider region as in FIGS. 9B-9E of the '161 patent. Other covering member configurations including those disclosed in the '161 patent could be utilized with the retainers of this present application.

The elongated covering member can be composed of materials such as polycarbonate or polyurethane. Preferably it is composed of resorbable materials such as lactide/glycolide copolymers that after a period of time resorb in the body. If composed of resorbable material, the covering member could optionally have regions of varying resorbability. Varying degrees of resorbability can be achieved for example by utilizing different materials having differing resorbable characteristics or by varying the mass of the covering member (increased mass increases resorbtion time).

Spherical retainers 20 and 22 are preferably composed of resorbable material. In a preferred embodiment, the diameter of each retainer 20, 22 is about 0.090 inches to about 0.095 inches, although other dimensions are contemplated. Although shown as spheres, other rounded shapes are also contemplated. The retainers could alternatively be made of non-absorbable polymeric or metallic material.

When the retainers 20 and 22 are released from the delivery instrument, they are spaced further from the covering member 40. They are then configured to be advanced toward the covering member 40. More specifically, each retainer 20, 22 is fixedly secured to a respective flexible connecting member such as suture 30, 32. Sutures 30, 32 are preferably made of polymeric material and are preferably resorbable, composed of a material such as polydioxanome. It is also contemplated that alternatively a metallic material could be utilized. The sutures, retainers and covering member can be made of the same or different resorbable material, and/or have the same or different resorption times.

As shown, suture 30 has a free end 30a and an opposite end 30b secured to retainer 20 by molding, gluing, forming a knot, or other methods. Similarly, suture 32 has a free end 32a and an opposite end 32b secured to retainer 22 in any of the foregoing manners. The suture is shown in the embodiment of FIG. 1 looped through the covering member. Other methods of attachment are also contemplated. For example, in the alternative embodiment of FIG. 8, sutures 150, 152 are attached to covering member 140 by a loop of suture 160. Loop 160 extends upwardly (proximally) from the covering member 140 and the sutures 150, 152 are looped through suture loop 160. Suture 160 can be attached to the covering member 140 by various methods such as insert molding or

by tying a knot in the suture under the covering member. In another alternate embodiment shown in FIG. 24, sutures 180, 182 are insert molded to a plug 190. The covering member 192 has a recess 194 to receive the plug 190. During manufacture, the plug 190 is wedged within the recess 194, 5 creating a tight frictional fit. The plug 190 is preferably flush with the distal surface 195 of covering member 192. Spherical retainers are designated by reference numerals 187, 188, are preferably identical to retainers 20, 22, and illustrated in the advanced position closer to proximal surface 197 of 10 covering member 192.

To advance the retainers 20, 22 toward the vessel wall (and covering member), the free end of each suture is pulled proximally (in a direction of the arrow of FIG. 4, thereby moving the respective retainer in the opposite direction 15 closer to the aperture A and vessel wall W. Once tightened against the tissue, a sufficient retention force is maintained, i.e. a proximal pulling force on the covering member 40 to pull it slightly proximally against the vessel wall. The retainers 20, 22 therefore help to prevent the covering 20 member 40 from separating from the vessel wall (e.g. moving in the direction toward the opposing vessel wall) which could create an unwanted gap between the covering member 40 and the vessel opening to allow blood flow. The extent to which the retainers 20, 22 move toward the wall 25 (and thus their distance from the vessel wall in their final placement position) will depend on the tissue thickness. Thus, the closure device can adjust for different tissue thicknesses and apply a constant retention force regardless of tissue thickness. The retainers of the other embodiments 30 disclosed herein function in a similar manner.

The delivery instrument for inserting the closure device extends through an opening in the skin, through the tissue tract to the vessel, through an external opening in the vessel wall, through the aperture in the vessel wall, and through an 35 internal opening on the internal side of the vessel wall into the vessel lumen.

The covering member 40 in FIG. 2 is outside retainer tube 50 and, within delivery sheath 60 in a tilted (pivoted) position. The covering member 40 emerges from the sheath 40 60 and moves from a tilted position, more aligned or in preferred embodiments substantially aligned with the longitudinal axis of the sheath, to a transverse position within the vessel (see FIG. 3). (Note the vessel wall is shown in FIG. 3 but the rest of the vessel and tissue are removed for clarity.) The retainers 20, 22 remain within tube 50. Note the covering member 40 can be ejected by a pusher (not shown) contacting the side or top wall. The retainers/covering members of the other embodiments disclosed herein can be delivered in a similar manner as that of retainers 20, 22 and 50 covering member 40.

As shown in FIG. 4 covering member 40 is pulled proximally to abut the internal opening on the internal side of the vessel W to cover (patch) the opening and the sutures extend through the opening A in the vessel wall. The first 55 retainer 20 is shown ejected from the delivery sheath 60 in FIG. 4 either by advancing the retainer, retracting the sheath after a counterforce is applied by engagement of the covering member with the vessel wall, or relative movement of both. The second retainer 22 is still within tube 50. The 60 second retainer 22 is then deployed in a similar manner as retainer 20 and is shown outside sheath 60 in FIG. 5. Note that in the delivery position, the retainers 20 and 22 are preferably in a stacked relationship (such as in FIG. 11) to minimize the transverse dimension of the delivery system. 65

Then, to retain the covering member 40 in position against the vessel wall to block blood flow therethrough, sutures 30 8

and 32 are pulled proximally from their free ends 30a, 32a in the direction of arrows B of FIG. 6, thereby advancing the retainers 20, 22 distally in the direction of arrows C toward the vessel wall V and covering member 40. As shown, the retainers 20, 22 can be moved to a position contiguous to the vessel wall, or depending on tissue thickness, may be adjacent the wall with some tissue interposed between the retainers and vessel wall. The retainers 20, 22 in this position apply a proximal force on the elongated covering member 40 to limit movement of the covering member into the vessel. The retainers in this placement position are preferably in a substantially side by side relationship as shown in FIG. 7.

As shown in FIG. 7, in the side by side relationship, the retainers 20 and 22 are alongside in a transverse orientation with respect to covering member 40. That is, they are positioned along the width of the covering member 40. However it is also contemplated that the retainers in the placement position can be in a lengthwise orientation (substantially parallel to the longitudinal axis of the covering member) as shown in FIG. 9 where corresponding components to FIG. 7 (e.g. retainers 20', 22', sutures 30', 32', covering member 40') have prime designations. The retainers could also be in other side by side arrangements at angles to the longitudinal axis. Alternatively, the retainers can be partially stacked in the placement position.

FIG. 10 illustrates an alternate embodiment of the closure device, designated by reference numeral 200. Closure device is substantially identical to closure device of FIG. 1 except for the knot at the end of the suture to retain the suture. More specifically, suture 232 has a free end 232a and a knotted end 232b with a knot 236 to retain spherical retainer 222. Similarly, suture 240 has a free end 240a and a knotted end 240b with a knot 246 to retain spherical retainer 220. The sutures are held in frictional engagement with a bore extending through the respective retainer 220,222. Covering member 290 is substantially identical to covering member 40 of FIG. 1 with the sutures attached thereto by a loop (not shown) as in FIG. 1. As the suture free ends 240a, 232a are pulled, the respective spherical retainers 220, 222 are advanced toward the covering member 240, as the knots 246, 236 abut the proximal end of the respective spherical retainers 220 and 222. Thus, the knots aid in the attachment of retainers 220, 222.

FIGS. 11-13C illustrate schematically a delivery system which can be utilized for placement of the closure devices described herein and shows schematically the device of FIG. 10 by way of example.

The delivery device includes a retainer tube 350 which is positioned within a delivery sheath (not shown). Retainer tube 350 has a distal opening 352 communicating with lumen 354 providing for passage of the retainers 220, 222 of closure device 200. Also positioned within the delivery tube 350 is a pusher tube 360 which is preferably solid except for two small lumens (not shown) dimensioned to receive a respective suture 240, 232.

In use, the retainer tube 350 with the retainers of the closure device contained within is placed in a delivery sheath (not shown). When positioned within the delivery sheath, the retainers 220, 222 are contained within the lumen 352 and the covering member 290 is positioned outside the retainer tube 350, and held in a longitudinal position by the walls of the delivery sheath. The covering member 290 is advanced from the delivery sheath into the vessel lumen by advancing the pusher tube 360 against the second retainer 222 in the direction of the arrow of FIG. 11. Since in the delivery position the second retainer 222 abuts the first

retainer 220 which abuts the covering member 290, advancement of the pusher tube 360 advances the covering member 290 from the delivery sheath.

Subsequently, the pusher tube 360 is moved further distally to advance the retainers 220, 222 from the retainer tube 5 350 as shown in FIG. 12. Next, the first retainer 220 is advanced toward the covering member as shown in FIGS. 13A, 13B by pulling the suture 240 from its proximal end in the direction of the arrow. After placement of the first retainer 220, the second suture 232 is pulled proximally in 10 the direction of the arrow of FIG. 13C to advance the second retainer 222 toward the covering member 290. The sutures can then be severed leaving the retainers 220, 222 and covering member 290 in place. It should be appreciated that these schematic views of FIGS. 11-13C omit the surrounding tissue and vessel portions for clarity. The covering member 290 is positioned inside the vessel lumen and the spherical retainers 220, 222 are positioned outside the vessel lumen.

FIGS. **14-18** illustrate an alternate embodiment of the 20 closure device having a configuration to restrict movement of the connecting member, e.g. the suture, which connects the retainer to the covering member.

More specifically, the closure device 400 of FIG. 14 is similar to the device 200 of FIG. 10 except the covering 25 member 490 has a first pair of holes 494a, 494b and a second pair of holes 496a, 496b. The first pair of holes 494a, 494b receive suture 440 and the second pair of holes 496a, 496b receive suture 430. Holes 494a, 496a have a smaller diameter than holes **494**b, **496**b. The larger hole **494**b is dimen- 30 sioned to receive suture 440 for free unrestricted movement of the suture 440 therethrough and therefore easier application of spherical retainer 420. Similarly, the larger hole 496b is dimensioned to receive suture 430 for free unrestricted movement of the suture 430 therethrough and therefore for 35 easier application (movement) of spherical retainer 422. Smaller hole 496a is dimensioned to frictionally engage suture 430 so that tension is applied to the suture 430. It is dimensioned so that the suture 430 can be pulled through the hole **496***a* if sufficient force is applied by pulling on free end 40 430a, but if such predetermined force is not applied, the suture will remain frictionally engaged within the wall of the opening 496a and not move. In this manner, when the user ceases pulling on free end 430a, the suture 430 and thus the spherical retaining ball 422 will remain in position. Suture 45 440 operates in a similar manner, with smaller opening 494a dimensioned to frictionally engage and resist movement of the suture 440 to retain spherical retainer 420. FIGS. 15-18 show how the suture is looped through the respective opening.

In an alternate embodiment, a plurality of internal teeth can be provided to enhance the retention of the suture within the smaller diameter hole. This is shown for example in FIGS. 22 and 23 wherein hole 496a' has a plurality of teeth 497 formed on the interior wall of the smaller opening. 55 Engagement of the suture 430' by the teeth 497 retains the suture 430 and spherical retainer. Note that the teeth 497 can be formed to angle inwardly so the suture 430 can be moved in only one direction, i.e. proximally so the retainer is advanced toward the covering member. Similar teeth can be 60 provided in the other small hole for retaining the other suture and retainer.

In the embodiment of FIG. 26, the opening 522 in covering member 520 has a triangular wedge shape region 523. The region 523 has a reduced size opening, narrowing 65 to a diameter less than an outer diameter of the suture 530 extending therethrough. The clinician can move the suture

10

530 into the narrow (reduced diameter) region 523 when desired to apply a gripping force on the suture 530 to retain the suture in place. Opening 524 is dimensioned larger than the outer diameter of the suture 530 to allow free unrestricted movement therethrough. Only one of the pair of openings is shown in the portion of the covering member 520 illustrated in FIG. 26, it being understood that a second similar pair of openings for the second suture can be provided. In all other respects the closure device can be identical to closure device 200 of FIG. 10 or other devices disclosed herein.

In the embodiment of FIG. 27, the retention of the suture is enhanced by inwardly directed bumps 560a, 560b, 560c and 560d on the underside of the covering member 570. That is, the suture (not shown) extending through large and small openings 570, 572, respectively, is gripped by the bumps 560a, 560b as the distance between opposing bumps is slightly less than the diameter of the suture. Sufficient tension (e.g. pulling force by the clinician), overrides the frictional force of the bumps 560 on the suture. Similarly a suture (not shown) extending through large and small openings 574, 576 is frictionally restrained by bumps 560c, 560d. The sutures connect retainers to the covering member 550 and are configured to be pulled to advance the retainers to the covering member in the manner described above with respect to the other embodiments. The bumps 560 can be utilized as a supplement to the small opening frictional engagement as is the embodiment of FIG. 14 or alternatively as the sole retention feature with two pairs of larger openings in the covering member.

FIGS. 19-21 illustrate an alternate embodiment of the closure device, designated generally by reference numeral 600, having a suture 610 extending transversely and joining spherical retainers 620 and 622. A knot 610a, 610b is formed on each end of the suture 610 to retain the retainers 620, 622. Connecting suture 630 has a looped proximal end 632 through which suture 610 extends. This loop 632 is tightened to secure suture 610. Both ends 631, 632 of the looped suture 630 extend though first opening 641 in covering member 640. End 632 terminates in knot 633 to connect suture 630 to covering member 640 (due to its diameter larger than opening 641). The other end 637 loops through covering member 640, exiting through opening 642 in suture portion 635.

Openings 642, 641 can be large and small openings functioning similar to the large and small openings of the embodiment of FIG. 14. That is, the openings can be configured to provide for free movement and tighter frictional engagement as in the embodiment of FIG. 14.

Pulling of suture end 630a advances the retainers 620, 622 together toward the covering member 640 due to the engagement of suture 630 with the transverse suture 610.

FIGS. 28-31 illustrate an alternate embodiment of the closure device, designated generally by reference numeral 700. Device 700 is similar to device 400 except for the way the suture and retainer are attached and the suture openings in the covering member. More specifically, closure device 700 has a first suture 730 and a second suture 740. Retainer 722, preferably spherical in configuration, is connected to suture 730 and retainer 720, preferably spherical, is connected to suture 740.

Covering member 790 has a first pair of holes 794a, 794b and a second pair of holes 796a, 796b. The first pair of holes 794a, 794b receive suture 740 and the second pair of holes 796a, 796b receive suture 730. Holes 794a, 796a have a smaller diameter than holes 794b, 796b. The larger hole 794b is dimensioned to receive suture 740 for free unre-

stricted movement of the suture **740** therethrough and therefore easier application of spherical retainer **720**. Similarly, the larger hole **796***b* is dimensioned to receive suture **730** for free unrestricted movement of the suture **730** therethrough and therefore for easier application (movement) of spherical 5 retainer **722**.

Smaller hole **796***a* is dimensioned to frictionally engage suture 730 so that tension is applied to the suture 730. It is dimensioned so that the suture 730 can be pulled through the hole **796***a* if sufficient force is applied by pulling on free end 730a, but if such predetermined force is not applied, the suture will remain frictionally engaged within the wall of the opening 796a and not move. As shown in the cross-sectional view of FIG. 31, the hole 796a has an inwardly angled wall 797 transitioning into a reduced diameter region 798 and an 15 outwardly angled wall 799 transitioning back to a larger diameter. The angled walls 797, 799 facilitate movement of the suture 730 when tension is applied, with the reduced diameter region 798 frictionally securing the suture. Hole 794a has a similar configuration as hole 796a and thus 20 contains similar angled walls. In this manner, when the user ceases pulling on free end 730a, the suture 730 and thus the spherical retaining ball 722 will remain in position. Suture 740 operates in a similar manner, with smaller opening 794a dimensioned to frictionally engage and resist movement of 25 the suture 740 to retain spherical retainer 720.

FIG. 32 illustrates one method of attachment of the suture to a spherical retainer. Spherical retainer 720 has a through hole 721 extending therethrough. Hole 721 has a first portion 721a having a first diameter and a second portion 721b 30 having a second larger diameter. A crimp or a bead 743 is attached to the suture 740, creating a diameter larger than the diameter of portion 721a. Thus, the wall of the through hole 721 forms a shoulder 723 to block movement of the spherical retainer 720. Preferably, the end 741 of the suture is 35 substantially flush with the spherical retainer 720. The crimp or bead is of substantial transverse dimension to frictionally engage the second portion 721b. Consequently, this frictional engagement prevents the retainer 720 from sliding in the direction away from the covering member 790 while the 40 shoulder 723 prevents the retainer 720 from sliding in the direction toward the covering member 790. The retainer 722 and suture 730 preferably have the same structure and engagement/retention as retainer 722 and suture 740.

In the alternate embodiment of FIG. 33, the suture 740' 45 has a knot 747 formed at its end. The shoulder 723' provides a stop for movement of retainer 720' away from covering member 790', as the diameter of portion 721a' of opening 721 is less than the transverse dimension of the knot 747. The knot 747 is of sufficient transverse dimension to frictionally engage the second portion 721b' to prevent the retainer 720' from sliding in the direction away from the covering member 790.

In the embodiment of FIGS. 34 and 35, a suture 834 forming a loop 835 has a knot 837 at one end. This suture 55 knot 837 frictionally engages portion 821b of the hole 821 formed in the retainer 820. A reduced diameter hole portion 821a forms a shoulder 823 to block movement of the knot 837. As shown, the looped end 835 of suture 834 receives suture 830. Consequently, tension applied to the ends 830a 60 of suture 830 pull the loop 835 upwardly (as viewed in the orientation of the FIG. 35) away from the covering member 890 to advance spherical retainer member 822 toward the covering member 890. A second suture 854 identical to suture 834 has a loop to receive suture 840 in the same 65 manner as suture 830. Suture 854 and 840 are identical to sutures 834 and 830, respectively, except that they function

12

to secure and move spherical retainer member 820. Consequently, when the ends 840a of suture 840 are pulled proximally, the suture 854, attached within an opening in the retainer 820 in the identical manner as suture 834, pulls the retainer 820 toward the covering member 890.

While the above description contains many specifics, those specifics should not be construed as limitations on the scope of the disclosure, but merely as exemplifications of preferred embodiments thereof. Those skilled in the art will envision many other possible variations that are within the scope and spirit of the disclosure as defined by the claims appended hereto.

What is claimed is:

- 1. A device for closing an aperture in a vessel wall, the aperture having an external opening in an external region of the vessel wall and an internal opening in an internal region of the vessel wall, the device comprising:
- a distal covering member positionable inside the vessel against the internal opening of the aperture, the covering member having a dimension to prevent egress of fluid through the aperture, the covering member having a first opening and a second opening spaced from the first opening;
- a proximal first retainer positionable external of the vessel and engageable with tissue to retain the distal covering member:
- a second retainer movable toward the covering member, the second retainer being movable independently of the first retainer:
- a flexible connecting member operatively connecting the covering member and the first retainer for placement of the closure device to close the aperture in the vessel wall, the first retainer fixedly secured to the flexible connecting member, the flexible connecting member advancing the first retainer toward the covering member, the first opening of the covering member configured to frictionally engage the flexible connecting member to restrict movement of the flexible connecting member until a predetermined force is applied which enables the flexible connecting member to move through the first opening, and the second opening having a larger diameter than the first opening for unrestricted movement of the flexible connecting member, wherein movement of the flexible connecting member in a proximal direction away from the covering member advances the first retainer toward the covering member in a distal direction as the flexible connecting member is moved through the first opening; and
- a second flexible connecting member, the second retainer attached to the second flexible connecting member and pulling of the second flexible connecting member advances the second retainer toward the covering member, the covering member having a third opening configured to restrict movement of the second flexible connecting member, and the second flexible connecting member is advanceable through the third opening until a predetermined force is applied and is not advanceable through the third opening if the predetermined force is not applied.
- 2. The device of claim 1, wherein the flexible connecting member comprises a first suture.
- 3. The device of claim 2, wherein the first retainer is spherical in configuration.
- 4. The device of claim 1, wherein the second retainer is spherical in configuration.

- **5**. The device of claim **1**, wherein the covering member is composed of a polymeric material.
- **6**. The device of claim **1**, wherein the covering member and first retainer are composed of a resorbable material.
- 7. The device of claim 1, wherein the covering member is 5 pivotable between a more longitudinal orientation for delivery and a transverse position for placement.
- 8. The device of claim 1, wherein the flexible connecting member has a first portion, a second free end portion, and an intermediate portion positioned between the first portion and the second portion, the first retainer is secured to the first portion and the intermediate portion loops through the covering member.
- **9**. A device for closing an aperture in a vessel wall, the aperture having an external opening in an external region of the vessel wall and an internal opening in an internal region of the vessel wall, the device comprising:
 - a distal covering member positionable inside the vessel against the internal opening of the aperture, the covering member having a dimension to prevent egress of ²⁰ fluid through the aperture, the covering member having a first opening and a second opening spaced from the first opening;
 - a proximal first retainer positionable external of the vessel and engageable with tissue to retain the distal covering ²⁵ member:
 - a flexible connecting member operatively connecting the covering member and the first retainer for placement of the closure device to close the aperture in the vessel wall, the first retainer fixedly secured to the flexible 30 connecting member, the flexible connecting member advancing the first retainer toward the covering member, the first opening of the covering member configured to frictionally engage the flexible connecting member to restrict movement of the flexible connecting member until a predetermined force is applied which enables the flexible connecting member to move through the first opening, and the second opening having a larger diameter than the first opening for unrestricted movement of the flexible connecting member, wherein movement of the flexible connecting member in a proximal direction away from the covering member advances the first retainer toward the covering member in a distal direction as the flexible connecting member is moved through the first opening, the flexible connecting member composed of a first suture:
 - a second suture and a second retainer attached to the second suture, the second suture advancing the second retainer toward the covering member; and
 - the first and second retainers are positioned in a substantially side by side non-stacked relationship in a placement position and are positioned in a stacked relationship one above the other in a delivery position.
- 10. The device of claim 9, wherein the covering member 55 has a third opening configured to restrict movement of the

14

second suture, and the second suture is advanceable through the third opening until a predetermined force is applied and is not advanceable through the third opening if the predetermined force is not applied.

- 11. The device of claim 10, further comprising a fourth opening in the covering member for unrestricted movement of the second suture.
- 12. The device of claim 9, wherein the first and second retainers and the first and second sutures are composed of a resorbable material.
- 13. The device of claim 9, wherein the covering member has a third opening having a first diameter smaller than a second diameter of a fourth opening to frictionally engage the second suture to restrict movement of the second suture.
- **14**. A device for closing an aperture in a vessel wall, the aperture having an external opening in an external region of the vessel wall and an internal opening in an internal region of the vessel wall, the device comprising:
 - a distal covering member positionable inside the vessel against the internal opening of the aperture, the covering member having a dimension to prevent egress of fluid through the aperture, the covering member having a first opening and a second opening spaced from the first opening;
 - a proximal first retainer positionable external of the vessel and engageable with tissue to retain the distal covering member;
 - a flexible connecting member operatively connecting the covering member and the first retainer for placement of the closure device to close the aperture in the vessel wall, the first retainer fixedly secured to the flexible connecting member, the flexible connecting member advancing the first retainer toward the covering member, the first opening of the covering member configured to frictionally engage the flexible connecting member to restrict movement of the flexible connecting member until a predetermined force is applied which enables the flexible connecting member to move through the first opening, and the second opening having a larger diameter than the first opening for unrestricted movement of the flexible connecting member, wherein movement of the flexible connecting member in a proximal direction away from the covering member advances the first retainer toward the covering member in a distal direction as the flexible connecting member is moved through the first opening, the flexible connecting member composed of a first suture:
 - a second suture and a second retainer attached to the second suture, the second suture advancing the second retainer toward the covering member; and
 - wherein in a placement position the first and second retainers are in a substantially side by side non-stacked relationship and in a transverse orientation with respect to the covering member.
